1 Short notes

1 · Format and Verify a Currency String

Formatting converts a value into a chosen textual representation. This example separates a literal currency symbol from an interpolated value, verifies the exact printed result, and states the limits of a display operation.

S1

2 Keyword index

2 terms; the number in brackets is the topic.

F-string (1). A formatted string literal that evaluates expressions inside braces. S1

Format specification (1). Text after a colon in a replacement field that controls presentation. S1

3 Rapid recall

1	Does adding a dollar sign convert a number into another currency?	No. The symbol is a display label. Conversion requires an explicitly supplied exchange rate and a defined calculation. S1

4 Last 10 minutes before the exam

Top facts

1. The example formats the integer exactly; it does not claim that floating-point arithmetic is suitable for all financial calculations. S1

Top formulas

E1.1 · Format two decimal places

```
price = 12
print(f"${price:.2f}")
```

gives	A currency-labelled display string.
applies	Python 3; this is display formatting and no exchange-rate conversion is implied.
units	Display text, not a currency conversion.
